1.5. Threat: Biological resource use
1.5 Threat: Biological resource use

1.5.1 Hunting and collecting terrestrial animals

Based on the collated evidence, what is the current assessment of the effectiveness of interventions for hunting and collecting terrestrial animals?

<table>
<thead>
<tr>
<th>Likely to be beneficial</th>
<th>• Reduce impact of amphibian trade</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unknown effectiveness (limited evidence)</td>
<td>• Use legislative regulation to protect wild populations</td>
</tr>
<tr>
<td>No evidence found (no assessment)</td>
<td>• Commercially breed amphibians for the pet trade</td>
</tr>
<tr>
<td></td>
<td>• Use amphibians sustainably</td>
</tr>
</tbody>
</table>

**Likely to be beneficial**

- **Reduce impact of amphibian trade**

One review found that reducing trade through legislation allowed frog populations to recover from over-exploitation. *Assessment: likely to be beneficial (effectiveness 76%; certainty 40%; harms 0%).*

http://www.conservationevidence.com/actions/824
Unknown effectiveness (limited evidence)

- **Use legislative regulation to protect wild populations**

One review found that legislation to reduce trade resulted in the recovery of frog populations. One study in South Africa found that the number of permits issued for scientific and educational use of amphibians increased from 1987 to 1990. *Assessment: unknown effectiveness – limited evidence (effectiveness 60%; certainty 30%; harms 5%).*

http://www.conservationevidence.com/actions/785

No evidence found (no assessment)

We have captured no evidence for the following interventions:

- Commercially breed amphibians for the pet trade
- Use amphibians sustainably

1.5.2 Logging and wood harvesting

| Likely to be beneficial | • Retain riparian buffer strips during timber harvest  
| Trade-off between benefit and harms | • Use shelterwood harvesting instead of clearcutting  
| Unknown effectiveness (limited evidence) | • Leave coarse woody debris in forests  
| Unlikely to be beneficial | • Use patch retention harvesting instead of clearcutting  
| Likely to be ineffective or harmful | • Leave standing deadwood/snags in forests  
| | • Use leave-tree harvesting instead of clearcutting  
| | • Harvest groups of trees instead of clearcutting  
| | • Thin trees within forests  

Likely to be beneficial

- **Retain riparian buffer strips during timber harvest**

  Six replicated and/or controlled studies in Canada and the USA compared amphibian numbers following clearcutting with or without riparian buffer strips. Five found mixed effects and one found that abundance was higher with riparian buffers. Two of four replicated studies, including one randomized, controlled, before-and-after study, in Canada and the USA found that numbers of species and abundance were greater in wider buffer strips. Two found no effect of buffer width. *Assessment: likely to be beneficial (effectiveness 50%; certainty 61%; harms 10%).*

- **Use shelterwood harvesting instead of clearcutting**

  Three studies, including two randomized, replicated, controlled, before-and-after studies, in the USA found that compared to clearcutting, shelterwood harvesting resulted in higher or similar salamander abundance. One meta-analysis of studies in North America found that partial harvest, which included shelterwood harvesting, resulted in smaller reductions in salamander populations than clearcutting. *Assessment: likely to be beneficial (effectiveness 40%; certainty 57%; harms 10%).*

Trade-off between benefit and harms

- **Leave coarse woody debris in forests**

  Two replicated, controlled studies in the USA found that abundance was similar in clearcuts with woody debris retained or removed for eight of nine amphibian species, but that the overall response of amphibians was more negative where woody debris was retained. Two replicated, controlled studies in the USA and Indonesia found that the removal of coarse woody debris from standing forest did not affect amphibian diversity or overall amphibian abundance, but did reduce species richness. One replicated, controlled study in the USA found that migrating amphibians used clearcuts where woody debris was retained more than where it was removed. One replicated, site comparison study in the USA found that within clearcut...
Amphibian Conservation

Forest, survival of juvenile amphibians was significantly higher within piles of woody debris than in open areas. *Assessment: trade-offs between benefits and harms* (effectiveness 40%; certainty 60%; harms 26%).

http://www.conservationevidence.com/actions/843

**Unknown effectiveness (limited evidence)**

- **Use patch retention harvesting instead of clearcutting**

  We found no evidence for the effect of retaining patches of trees rather than clearcutting on amphibian populations. One replicated study in Canada found that although released red-legged frogs did not move towards retained tree patches, large patches were selected more and moved out of less than small patches. *Assessment: unknown effectiveness – limited evidence* (effectiveness 20%; certainty 25%; harms 0%).

  http://www.conservationevidence.com/actions/847

**Unlikely to be beneficial**

- **Leave standing deadwood/snags in forests**

  One randomized, replicated, controlled, before-and-after study in the USA found that compared to total clearcutting, leaving dead and wildlife trees did not result in higher abundances of salamanders. One randomized, replicated, controlled study in the USA found that numbers of amphibians and species were similar with removal or creation of dead trees within forest. *Assessment: unlikely to be beneficial* (effectiveness 5%; certainty 58%; harms 2%).

  http://www.conservationevidence.com/actions/845

- **Use leave-tree harvesting instead of clearcutting**

  Two studies, including one randomized, replicated, controlled, before-and-after study, in the USA found that compared to clearcutting, leaving a low density of trees during harvest did not result in higher salamander abundance. *Assessment: unlikely to be beneficial* (effectiveness 10%; certainty 48%; harms 11%).

  http://www.conservationevidence.com/actions/846
Likely to be ineffective or harmful

- **Harvest groups of trees instead of clearcutting**
  Three studies, including two randomized, replicated, controlled, before-and-after studies, in the USA found that harvesting trees in small groups resulted in similar amphibian abundance to clearcutting. One meta-analysis and one randomized, replicated, controlled, before-and-after study in North America and the USA found that harvesting, which included harvesting groups of trees, resulted in smaller reductions in salamander populations than clearcutting. Assessment: likely to be ineffective or harmful (effectiveness 33%; certainty 60%; harms 23%).

  [http://www.conservationevidence.com/actions/844](http://www.conservationevidence.com/actions/844)

- **Thin trees within forests**
  Six studies, including five replicated and/or controlled studies, in the USA compared amphibians in thinned to unharvested forest. Three found that thinning had mixed effects and one found no effect on abundance. One found that amphibian abundance increased following thinning but the body condition of ensatina salamanders decreased. One found a negative overall response of amphibians. Four studies, including two replicated, controlled studies, in the USA compared amphibians in thinned to clearcut forest. Two found that thinning had mixed effects on abundance and two found higher amphibian abundance or a less negative overall response of amphibians following thinning. One meta-analysis of studies in North America found that partial harvest, which included thinning, decreased salamander populations, but resulted in smaller reductions than clearcutting. Assessment: likely to be ineffective or harmful (effectiveness 35%; certainty 60%; harms 40%).
